Abstract

Physics is facing contingency. Not only in facts but also in laws (the frontier becoming extremely narrow). Cosmic natural selection is a tantalizing idea to explain the apparently highly improbable structure of our Universe. In this brief note I will study the creation of Universes by black holes in –string inspired– higher order curvature gravity.

Keywords : Anthropic principle, Lovelock black holes, String gravity.

Cosmology is a very strange branch of physics which contradicts nearly all the heuristic principles of the Science of Nature : the observer is part of the system described, the experiment "creation of the Universe" is unique (or has long been thought to be), the boundary conditions are relevant for the fundamental laws, the history must be extrapolated backward in time –as forbidden by the second law of thermodynamics– and the energy scales considered are well above all that can be probed by laboratory experiments. Beyond all such specific features, this framework makes it unavoidable to question ourselves about the *necessity* of things and rules as they now appear. Among possible values of fundamental parameters, those leading to the "kind of Universe" we know are often located in a zero measure phase space. This surprising situation could be naturally understood if there is not a single Universe but many (maybe an infinity) of them with different realizations of the science laws, as suggested by the string landscape [1]. We simply live in one of them which is compatible with the existence of our *specific* life (the literature on the anthropic principle is very rich, a good up-to-date summary is given in [2] by Brandon Carter who first introduced this concept in modern cosmology). The idea of multiple Worlds, which is necessary for this viewpoint to be conclusive beyond a simple space selection effect, is far from being new or revolutionary. It was probably introduced by Anaximander and Democritus in ancient Greece, revisited by Nicholas from Cusa and Giordano Bruno at the beginning of Renaissance (together with Rabelais refering to the Pythagorean philosopher Petron) before being –with very different meanings– considered by Leibniz and Spinoza in the XVII$^{\text{th}}$ century. Since this time, it has never been abandoned. In contemporary philosophy, following somehow the "Pluralistic Universe" of William James, it lies at the basis of many thoughts from Goodman [5], Foresta [6], Hintikka [7] and Lewis [8], among many others.

As far as physics in concerned, I will focus in the following on the proposal from Lee Smolin [4] (which has already been objected some pertinent arguments [9]) where black holes are considered as creators of new Universes. This alternative to the more popular view where chaotic inflation plays this role is motivated by its ability to allow for inherited characters (what I will call a Lamarck Universe), to rely on better understood physical grounds and to develop a causal structure for selection effects to occur. In this scenario, our Universe would have been

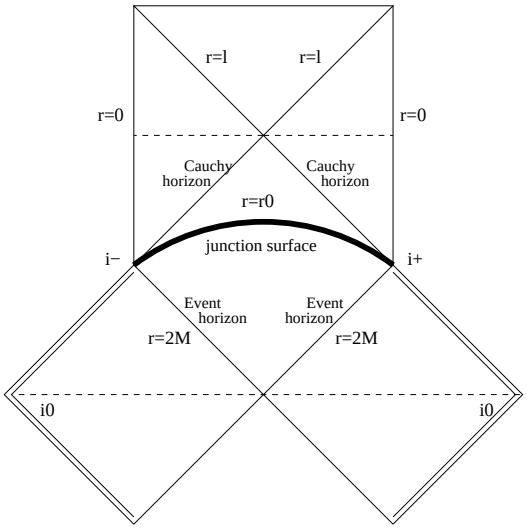

Figure 1: Conformal Penrose-Carter diagram for a Scwarzschild black hole with a de Sitter interior [11].

born from a black hole in another Universe and would have generated at least 10^{15} Universes through the black holes it certainly contains (this could have interesting implications on the usual question about the surprisingly small value of the entropy of our Universe). The main idea relies on bouncing which is quite well established for cosmological models but remains quite controversial in the black hole sector. Frolov, Markov & Mukhanov [11] have shown how the Schwarzschild metric inside a black hole can be attached to the de Sitter one at some spacelike junction surface leading to the spacetime displayed in Fig. 1.

In addition to controversial postulates about the equation of state close to the central singularity ($R^2 = 4R^\nu_\mu R^\mu_\nu$), the basic assumption is the existence of a limiting curvature : $R_{\mu\nu\lambda\rho}R^{\mu\nu\lambda\rho} < \alpha/l^4$ where l has the dimension of a length (expected to lie close to the Planck size) and $\alpha \sim 1$.

This *ad hoc* assumption can be investigated in the framework of string gravity, which is expected to account for *some* quantum effect in the gravitational sector. Let us consider first the general 4-dimensional effective string action with second order curvature corrections :

$$S = \frac{1}{16\pi}\int d^4x\sqrt{-g}\Big[-R + 2\partial_\mu\phi\partial^\mu\phi + \lambda_2 e^{-2\Phi}(R_{\mu\nu\lambda\rho}R^{\mu\nu\lambda\rho} - 4R_{\mu\nu}r^{\mu\nu} + R^2)\Big].$$

This Lagrangian is well known for appearing in the limit of different string theories [12]. It can also be viewed as a second order truncature of Lovelock gravity –made dynamical in 4 dimensions through the dilatonic coupling– which can be seen as the sum of dimensionally extended Euler densities. The full Lagrangian density (which corresponds to the most general tensor that can be equaled to the stress-energy tensor while keeping the mathematical structure of the theory) reads as [13]

$$L = \Sigma_{n=0}^k c_n L_n \text{ with } L_n = 2^{-n}\delta^{a_1b_1a_nb_n}_{c_1d_1c_nd_n}R^{c_1d_1}{}_{a_1b_1}...R^{c_nd_n}{}_{a_nb_n},$$

where c_i are constants, δ is totally antisymmetric in both sets of indices and L_n is the Euler density of a 2n-dimensional manifold.

In any attempt to perturbatively quantize gravity as a field theory, higher-derivative interactions must be included in the action. Furthermore, higher-derivative gravity theories are

intrinsically attractive as in many cases they display features of renormalizability and asymptotic freedom. Among such approaches, Lovelock gravity [14] is especially interesting as the resulting equations of motion contain no more than second derivatives of the metric, include the self interaction of gravitation, and are free of ghosts when expanding around flat space. The four-derivative Gauss-Bonnet term is most probably the dominant correction to the Einstein-Hilbert action [15]. Gauss-Bonnet gravity was shown to exhibit a very rich phenomenology in cosmology (see, *e.g.*, [16] and references therein), high-energy physics (see, *e.g.*, [17] and references therein) and black hole theory (see, *e.g.*, [18] and references therein). It also provides interesting solutions to the dark energy problem [19], offers a promising framework for inflation [20], allows useful modification of the Randall-Sundrum model [21] and, of course, solves most divergences associated with the endpoint of the Hawking evaporation process [22].

Those Gauss-Bonnet black-holes can be studied with the choice of metric :

$$ds^2 = \Delta dt^2 - \frac{\sigma^2}{\Delta} dr^2 - f^2(d\theta^2 + \sin^2\theta d\varphi^2).$$

Integrating numerically (using an additional parameter) inside the event horizon r_h allows to show [18] that a solution exists only up to a (lower) value of the radius $r = r_s$. A new branch exists between r_s and a singular horizon r_x but its physical meaning is unclear. The main point I want to underline is that the curvature invariant can be computed [18] around the minimal radius r_s with the parameterization $x = \sigma - \sigma_s$:

$$\begin{aligned} R_{\mu\nu\rho\lambda}R^{\mu\nu\rho\lambda} &= 4\frac{\Delta^2}{\sigma^4 r^4} + 8\frac{\Delta^2(\sigma')^2}{\sigma^6 r^2} - 8\frac{\Delta}{\sigma^2 r^4} - 8\frac{\Delta\Delta'\sigma'}{\sigma^5 r^2} + \frac{(\Delta'')^2}{\sigma^4} \\ &+ 4\frac{(\Delta')^2}{\sigma^4 r^2} - 2\frac{\Delta''\Delta'\sigma'}{\sigma^5} + \frac{(\Delta')^2(\sigma')^2}{\sigma^6} + \frac{4}{r^4} \\ &= \frac{1}{x^2}\left(\frac{4d_s}{r_2 r_s^2 \sigma_s^6} + \frac{d_2}{2r_2^2\sigma_s^6}\right) + O\left(\frac{1}{x}\right) \to \infty \end{aligned}$$

where d_2 and d_s are expansion coefficients.

This means that **although the correct topology $S^2 \times R^1$ (an infinite –in the t direction– tube of radius r_s) naturally arises in this approach, the expected regularization of the Riemann invariant does not occur.** From this viewpoint, Gauss-Bonnet gravity disfavours black holes as Universe-makers. Of course, this theory remains a low-energy effective description and one can still hope that a full quantum gravitational treatment changes this conclusion.

The point made here is nevertheless quite robust for two reasons. First, because it remains true when a Maxwell term $e^{-2\Phi}F_{\mu\nu}F^{\mu\nu}$ is added to the action, at least up to a critical value q_{cr} (of the order of $\approx 0.3 r_h$ in Planck units) which was numerically determined in [23]. When $q < q_{cr}$, the topology of the solution is unchanged and $R_{\mu\nu\lambda\rho}R^{\mu\nu\lambda\rho} \to \infty$ (the case $q_{cr} < q < m\sqrt{2}$ is interesting and should be studied in this perspective). Then, because it remains stable under higher order curvature corrections of string gravity. As an example, the fourth order action reads as

$$\begin{aligned} S &= \frac{1}{16\pi}\int d^4x\sqrt{-g}\Big[-R + 2\partial_\mu\phi\partial^\mu\phi \\ &+ \lambda_2 e^{-2\phi}L_2 + \lambda_3 e^{-4\phi}L_3 + \lambda_4 e^{-6\phi}L_4 + \ldots\Big]. \end{aligned}$$

In this expression, L_2 denotes the second order curvature correction (Gauss-Bonnet term), L_3 is the third order curvature correction,

$$\begin{aligned} L_3 &= 3R^{\mu\nu}_{\alpha\beta}R^{\alpha\beta}_{\lambda\rho}R^{\lambda\rho}_{\mu\nu} - 4R^{\mu\nu}_{\alpha\beta}R^{\lambda\beta\rho}_{\nu}R^{\alpha}_{\rho\mu\lambda} + \frac{3}{2}RR^2_{\mu\nu\alpha\beta} + 12R^{\mu\nu\alpha\beta}R_{\alpha\mu}R_{\beta\nu} \\ &+ 8R^{\mu\nu}R_{\nu\alpha}R^{\alpha}_{\mu} - 12RR^2_{\alpha\beta} + \frac{1}{2}R^3, \end{aligned}$$

and L_4 stands for the fourth order curvature correction,

$$\begin{aligned} L_4 &= \zeta(3)\left[R_{\mu\nu\rho\sigma}R^{\alpha\nu\rho\beta}\left(R^{\mu\gamma}_{\delta\beta}R^{\delta\sigma}_{\alpha\gamma}\right)\right] - \xi_h\left[\frac{1}{8}\left(R_{\mu\nu\alpha\beta}R^{\mu\nu\alpha\beta}\right)^2\right. \\ &+ \left.\frac{1}{4}R^{\gamma\delta}_{\mu\nu}R^{\rho\sigma}_{\gamma\delta}R^{\gamma\delta}_{\rho\sigma}R^{\mu\nu}_{\gamma\delta} - \frac{1}{2}R^{\alpha\beta}_{\mu\nu}R^{\rho\sigma}_{\alpha\beta}R^{\mu}_{\sigma\gamma\delta}R^{\nu\gamma\delta}_{\rho} - R^{\alpha\beta}_{\mu\nu}R^{\rho\nu}_{\alpha\beta}R^{\gamma\delta}_{\rho\sigma}R^{\mu\sigma}_{\gamma\delta}\right] \\ &- \frac{1}{2}\xi_B\left[\left(R_{\mu\nu\alpha\beta}R^{\mu\nu\alpha\beta}\right)^2 - 10R_{\mu\nu\alpha\beta}R^{\mu\nu\alpha\sigma}R_{\sigma\gamma\delta\rho}R^{\beta\gamma\delta\rho} - R_{\mu\nu\alpha\beta}R^{\mu\nu\rho}_{\sigma}R^{\beta\sigma\gamma\delta}R^{\alpha}_{\delta\gamma\rho}\right]. \end{aligned}$$

The coefficients c_i and ξ_i just depend upon the type of string theory considered. It can in any case (expect for SUSY-II were the situation is still unclear) be explicitly shown [24] that the structure of the singularities is unchanged and the Riemann invariant still diverges. In a way, the situation is therefore even worst than in usual general relativity as this occurs at finite distance from the center of the black hole.

The main point here is that perturbative string corrections seem to disfavor the hypothesis of a limiting curvature which would have allowed for a junction layer between a Schwarzschild space and a de Sitter space within black holes. Otherwise stated, Gauss-Bonnet black holes are not very promising Universes progenitors although they seem to be free of the most dramatic problems associated with quantum gravity effects (in particular when considering the endpoint of the Hawking evaporation process).

On the other hand, it is very interesting to notice that other approaches, *e.g.* taking into account nonperturbative semiclassical effects in loop quantum gravity [25], reach exactly the opposite conclusion ! This clearly refects our lack of understanding of the real quantum regime in the gravitational sector.

The multiverse hypothesis –whether falsifiable or not[1]– offers a very rich framework to elaborate both on the world(s) and on our scientific creations about the world(s). It is not even clear that it makes sense to distinguish between both proposals. The structure of time itslef could appear as radically modified (see, *e.g.*, [26] and references therein). Using the string landscape to argue in favor of this model is probably a bit naïve as this still relies on an assumed *single* meta-theory. This "pluriverse" is maybe not that pluralistic[2]... As often (as usual ?) this could tell us much more about the schemes of our mental activities than about the intrinsic structure of reality[3]. But it could very well be that physics is now taking distances with a kind of implicit ontological commitment. Physics faces contingency. An exciting situation !
